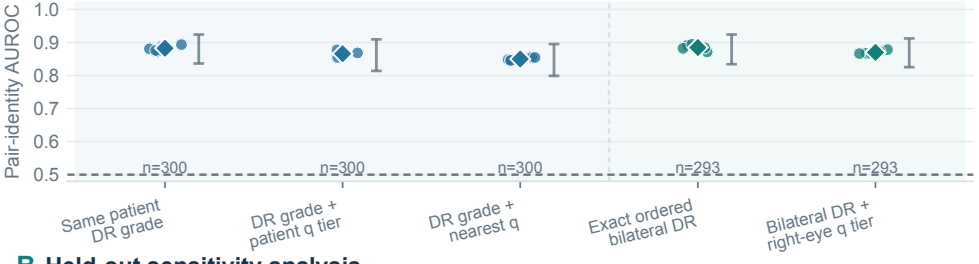
CONDITIONAL CONTROLS

Correspondence persists under stricter eye-level controls

Five fixed negative assignments per condition; points show seedwise AUROC, diamonds show mean ± sample SD.

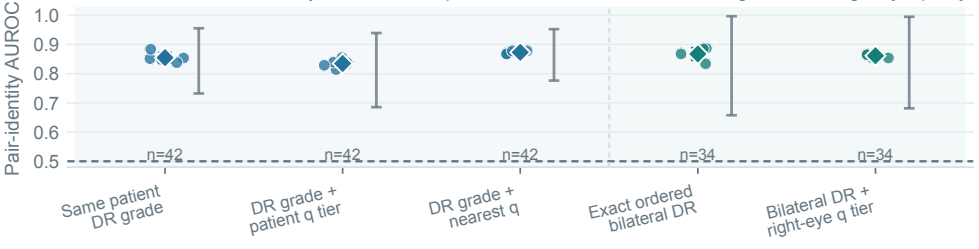
A Full-cohort diagnostic

Original patient-level controls (n=300) versus post-hoc exact bilateral-signature controls (n=293).



B Held-out sensitivity analysis

Post-hoc common-denominator analyses; the stricter protocol matches bilateral disease signature and right-eye quality tier.



Thin offset whiskers: envelope of five separate 95% patient-node bootstrap intervals (conditional on fixed assignments; not pooled). The two matching schemes use different quality aggregation levels; AUROC differences are not causal effects.
